Overview

Maximal matching

Maximal independent set

We will talk about **lower bounds** for solving these problems in the **distributed setting**

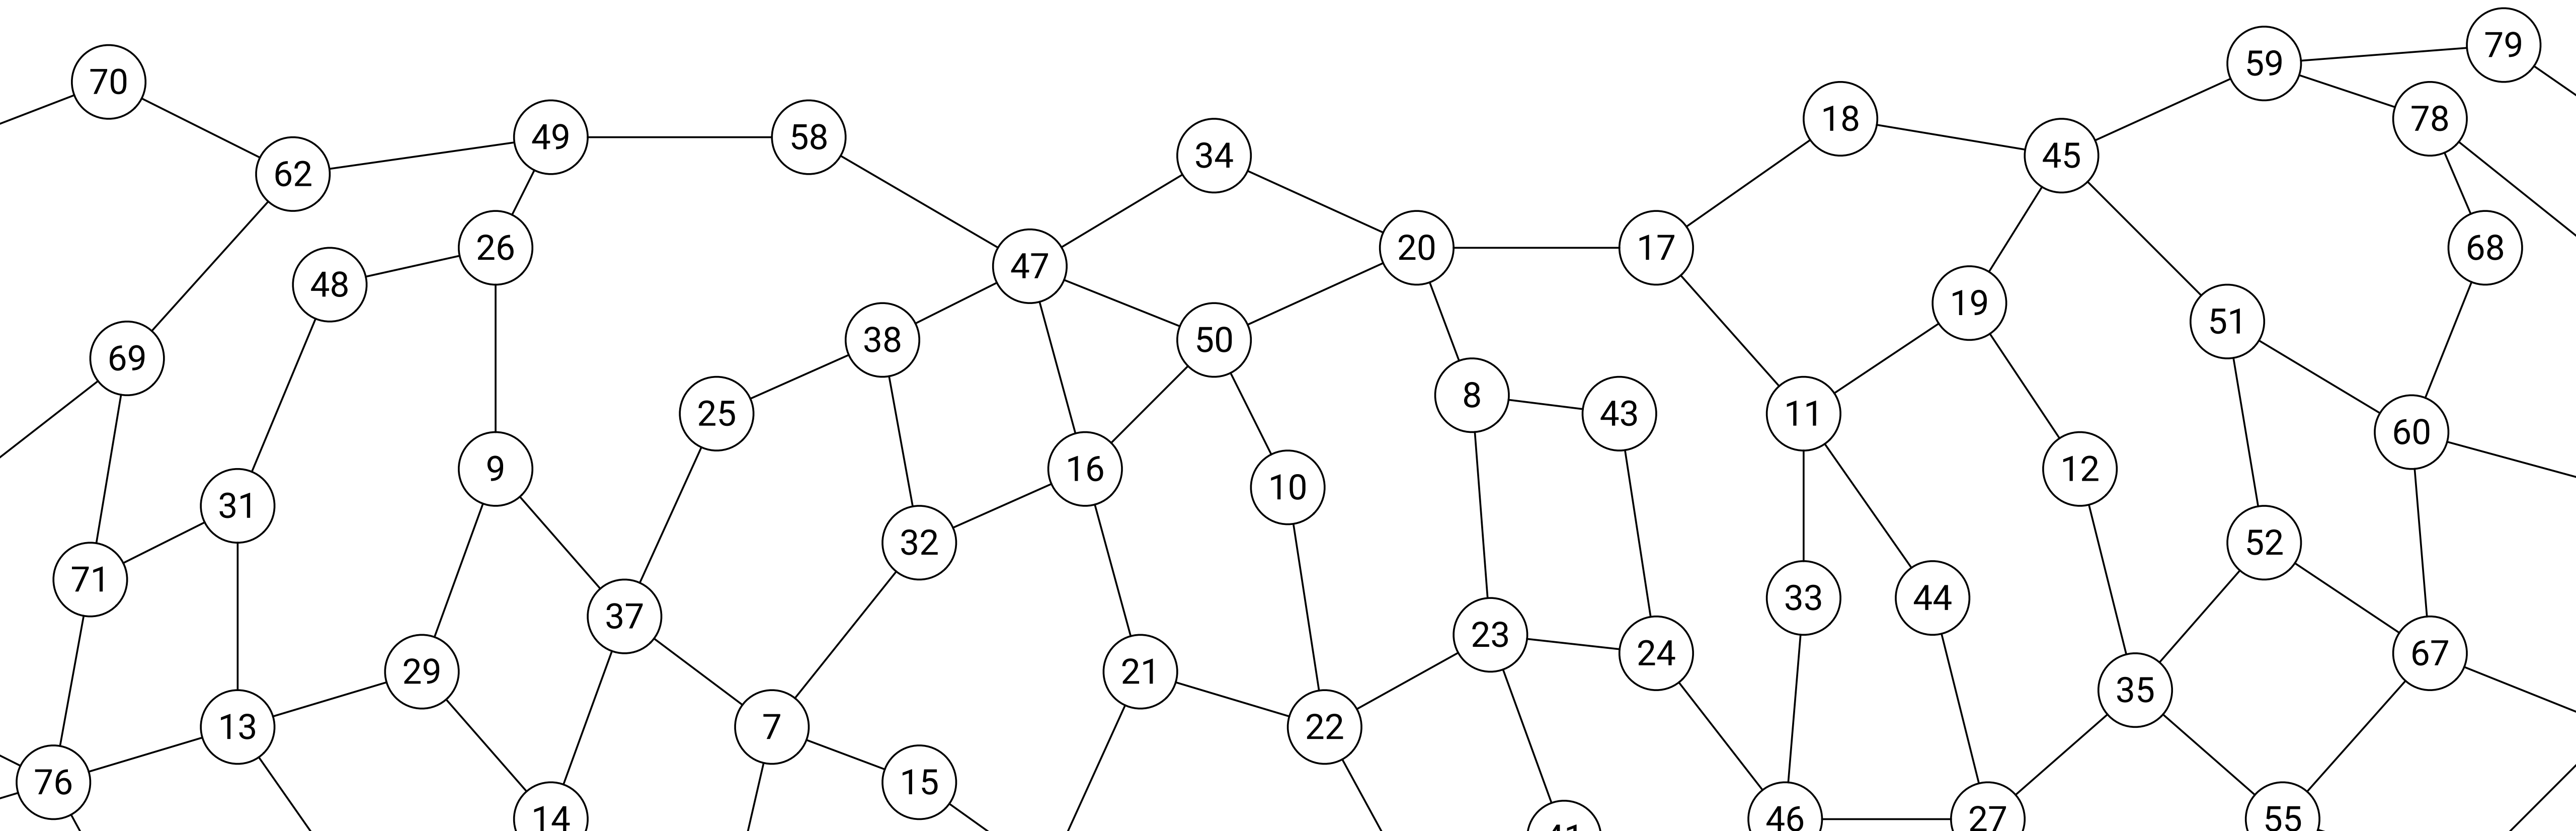

Distributed setting

- Entities = **nodes**
- Communication links = **edges**
- Input graph = communication graph

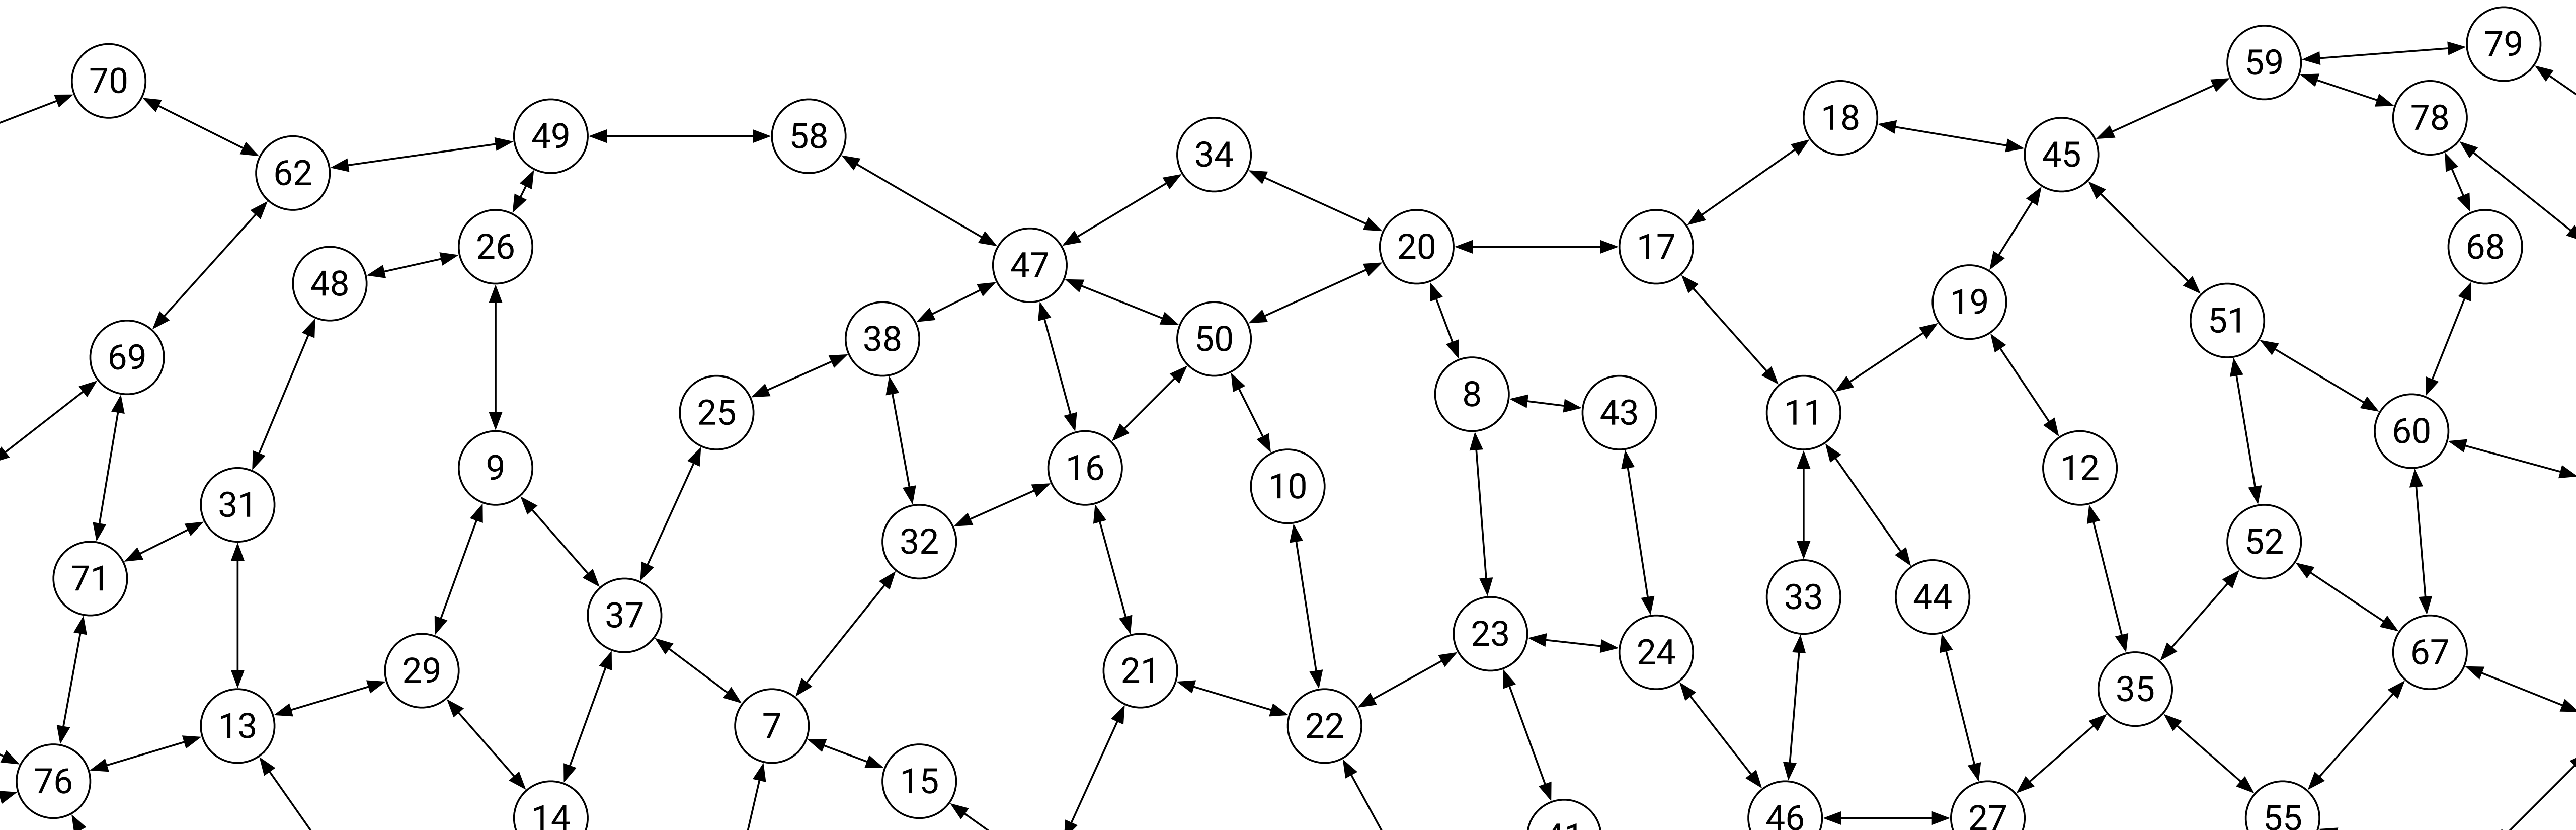

Distributed setting

- Entities = **nodes**
- Communication links = **edges**
- Input graph = communication graph

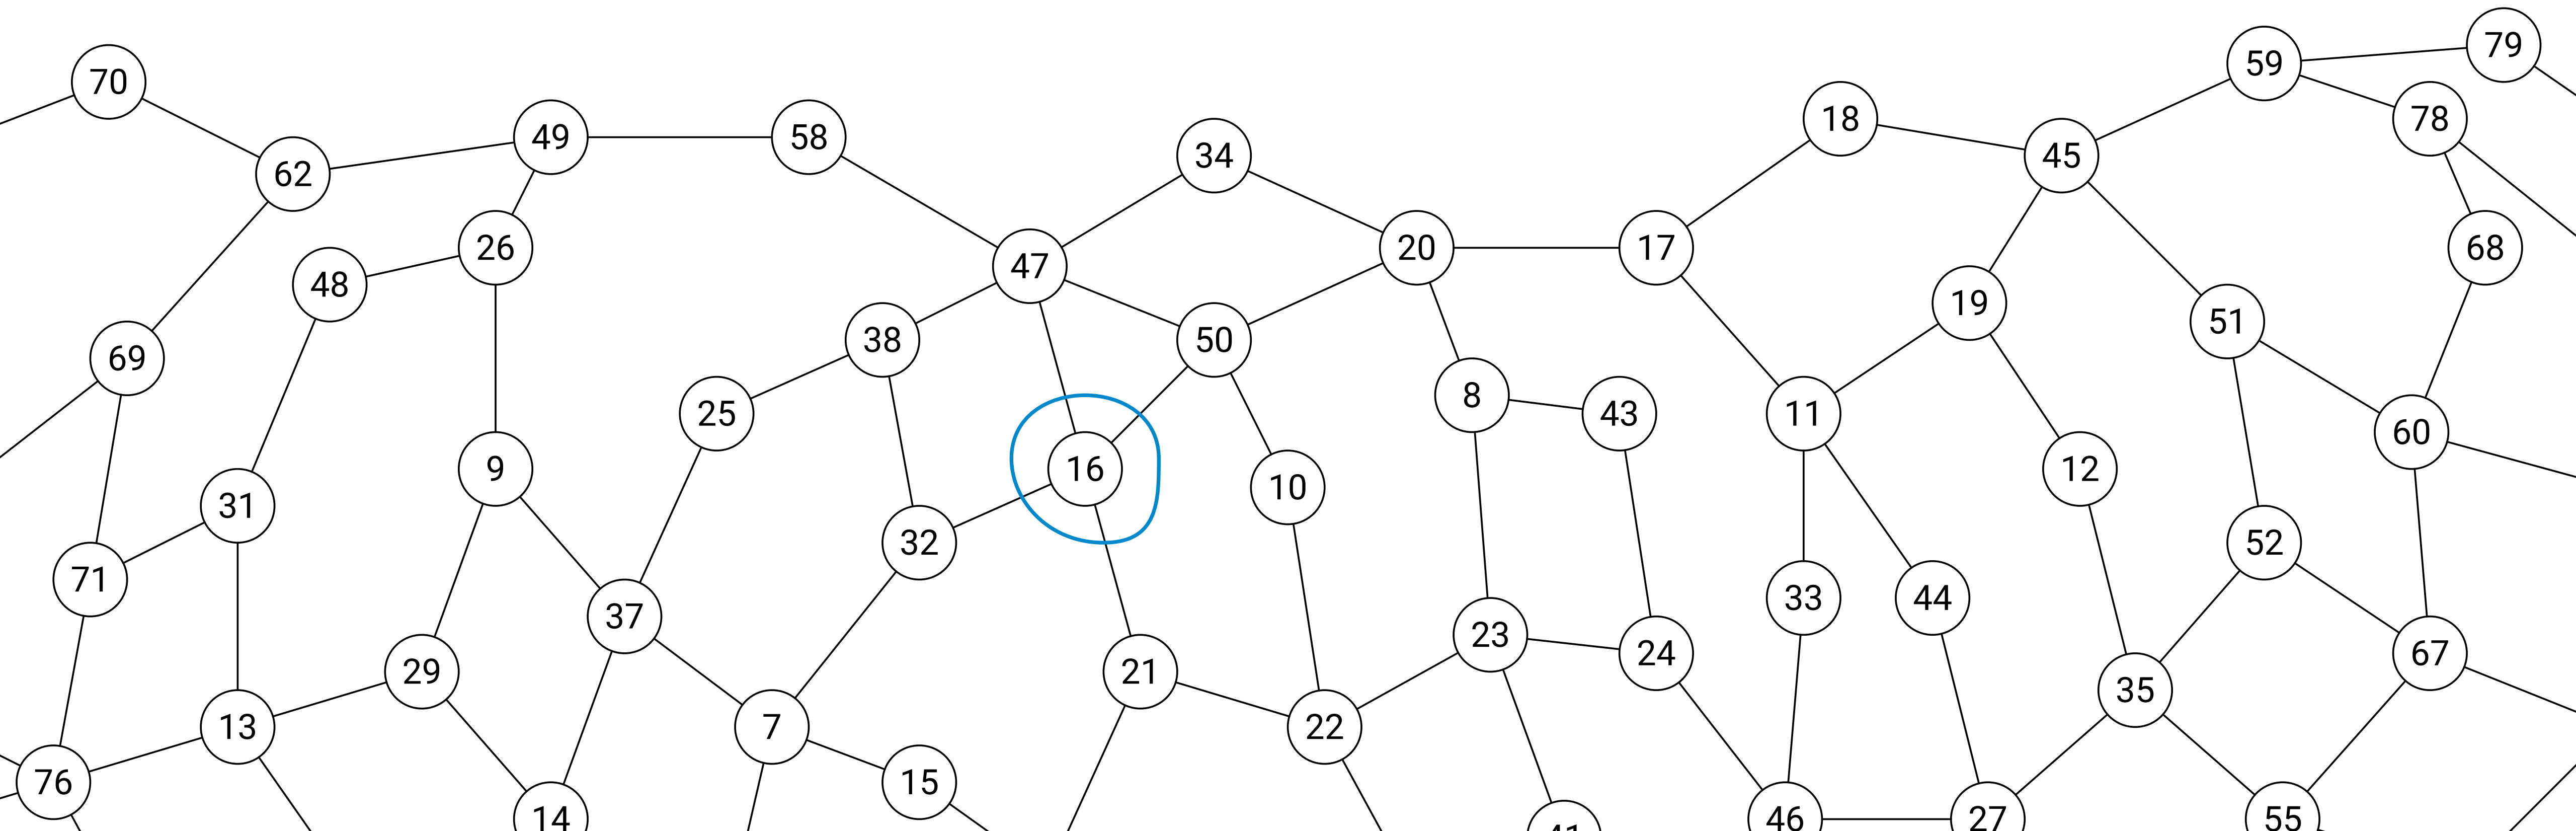

Distributed setting

- Entities = **nodes**
- Communication links = **edges**
- Input graph = communication graph

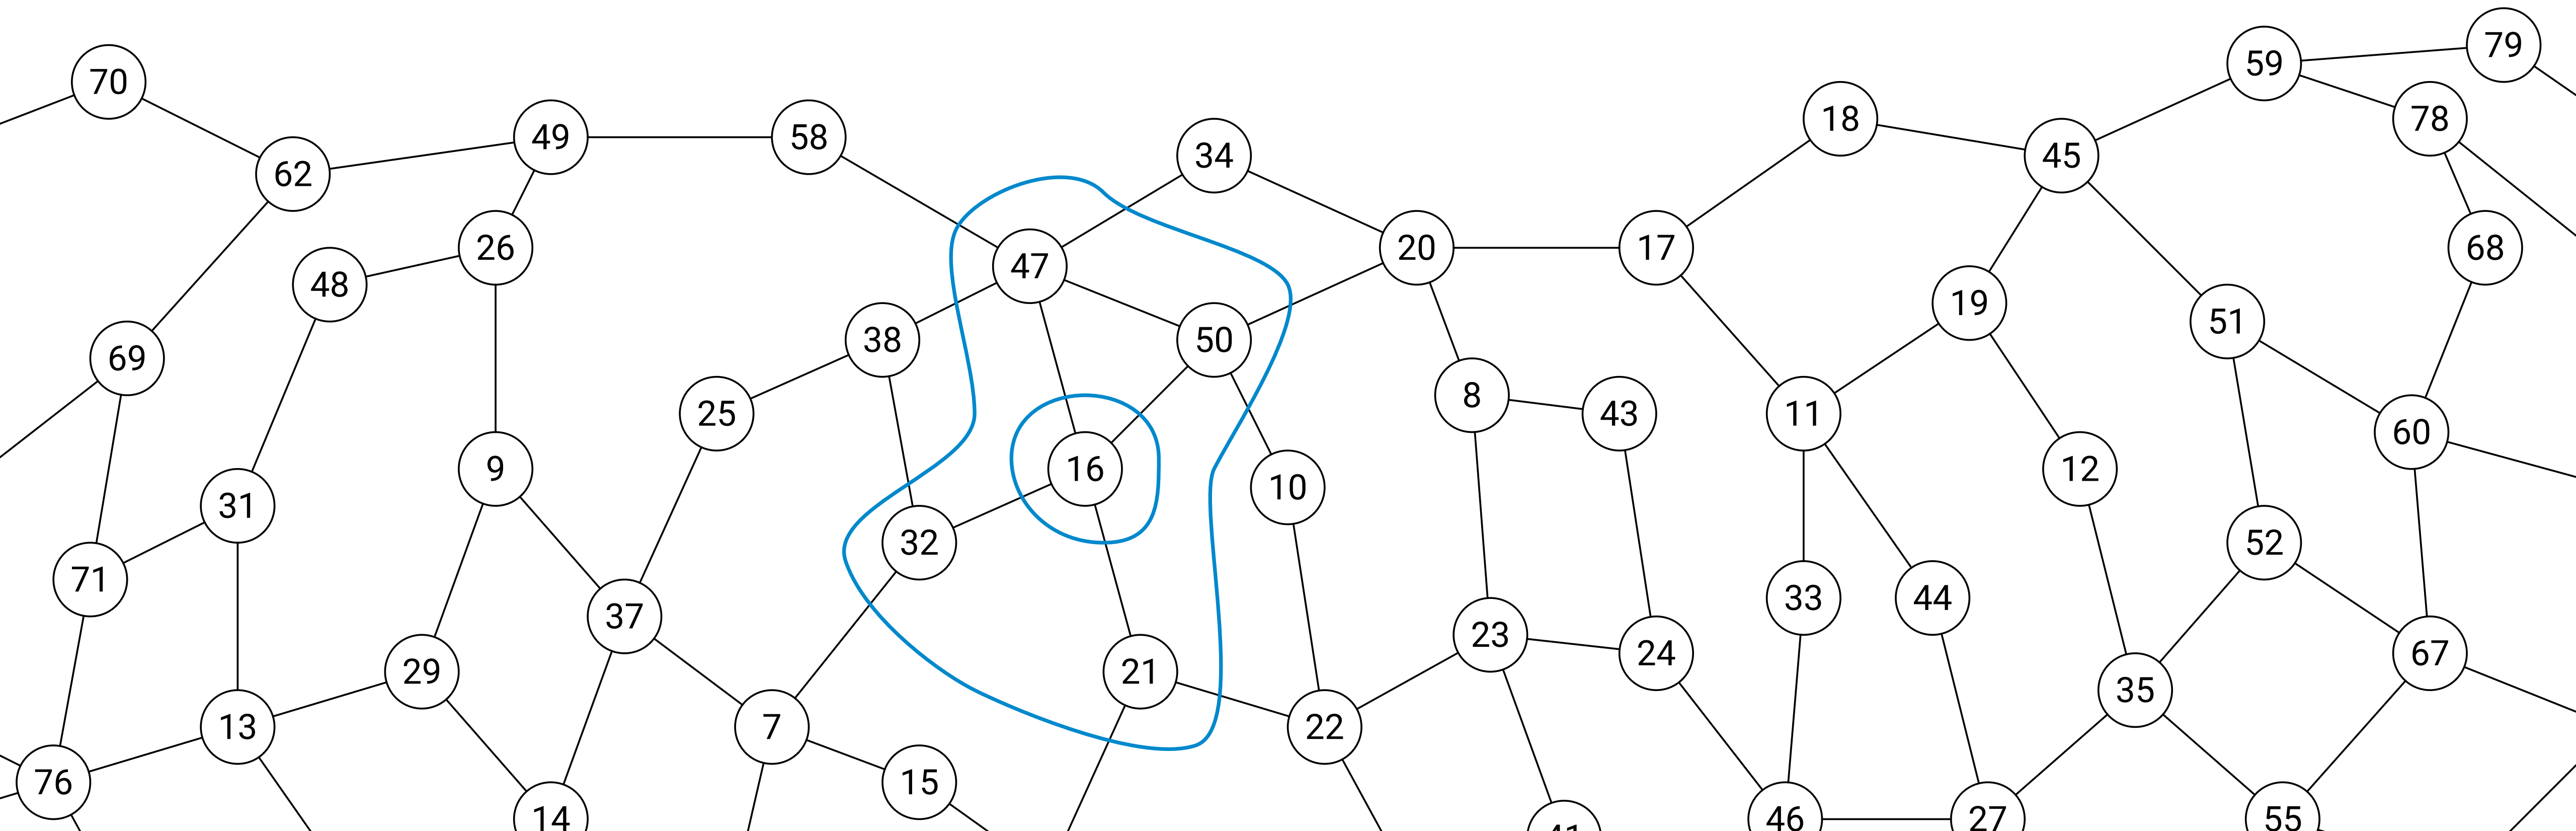

Distributed setting

- Entities = **nodes**
- Communication links = **edges**
- Input graph = communication graph

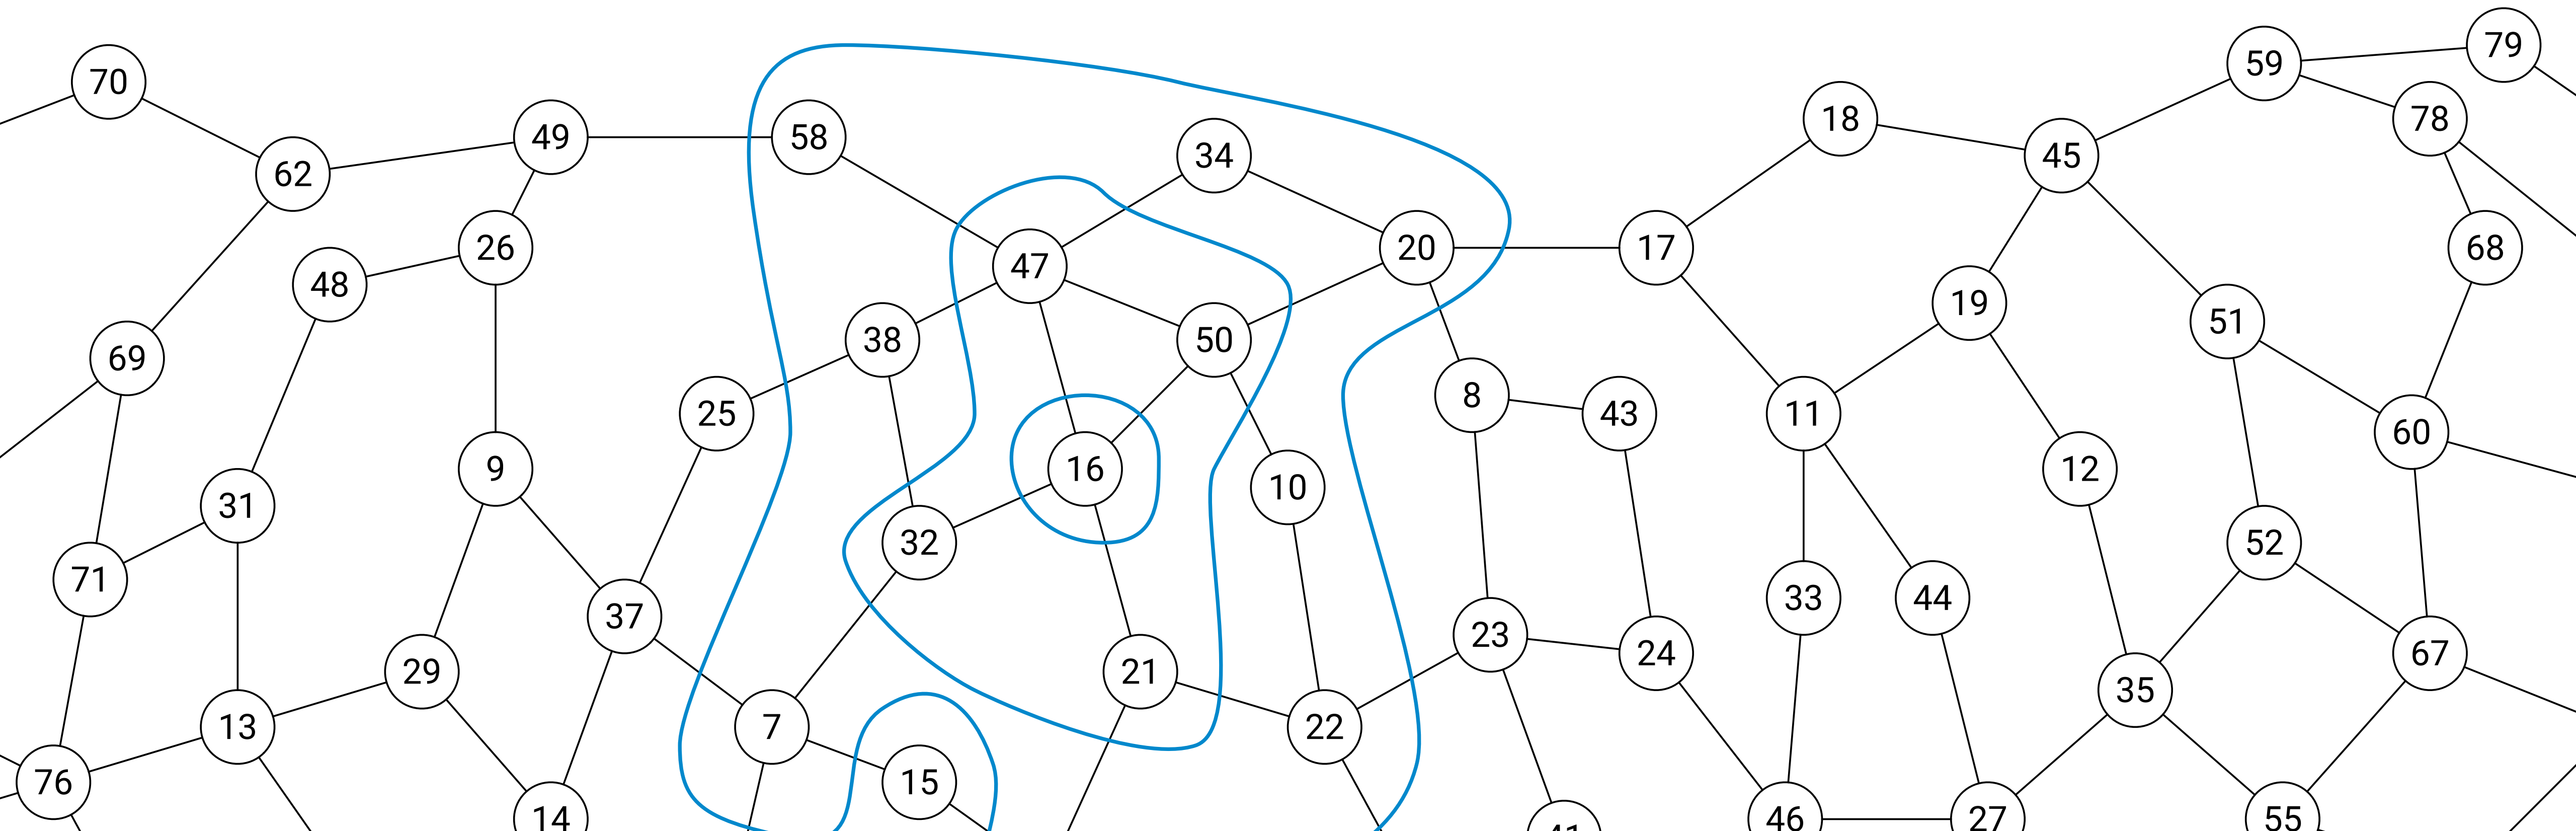

Distributed setting

- Entities = **nodes**
- Communication links = **edges**
- Input graph = communication graph

Distributed setting

- Entities = **nodes**
- Communication links = **edges**
- Input graph = communication graph

Maximal matching problem

Input

Output

- **Matching**: edges in the matching do not share a node
- **Maximality**: if we add any other edge in the matching, than it is not a matching anymore
- We say that **a node is matched**: it is an endpoint of an edge in the matching

Maximal independent set problem

Input

Output

- **Independent set**: nodes in the IS do not share an edge
- **Maximality**: if we add any other node to the IS, than it is not independent anymore

Two classical graph problems

Maximal matching

Maximal independent set

Easy linear-time **centralized** algorithm:
add edges/nodes until stuck

Two classical graph problems

Maximal matching

Maximal independent set

Can be **verified locally**: if it looks correct everywhere locally, it is also feasible globally

Can these problems be **solved locally**?

Locality = how far do I need to see to produce my own part of the solution?

Warmup: toy example

Bipartite graphs & port-numbering model

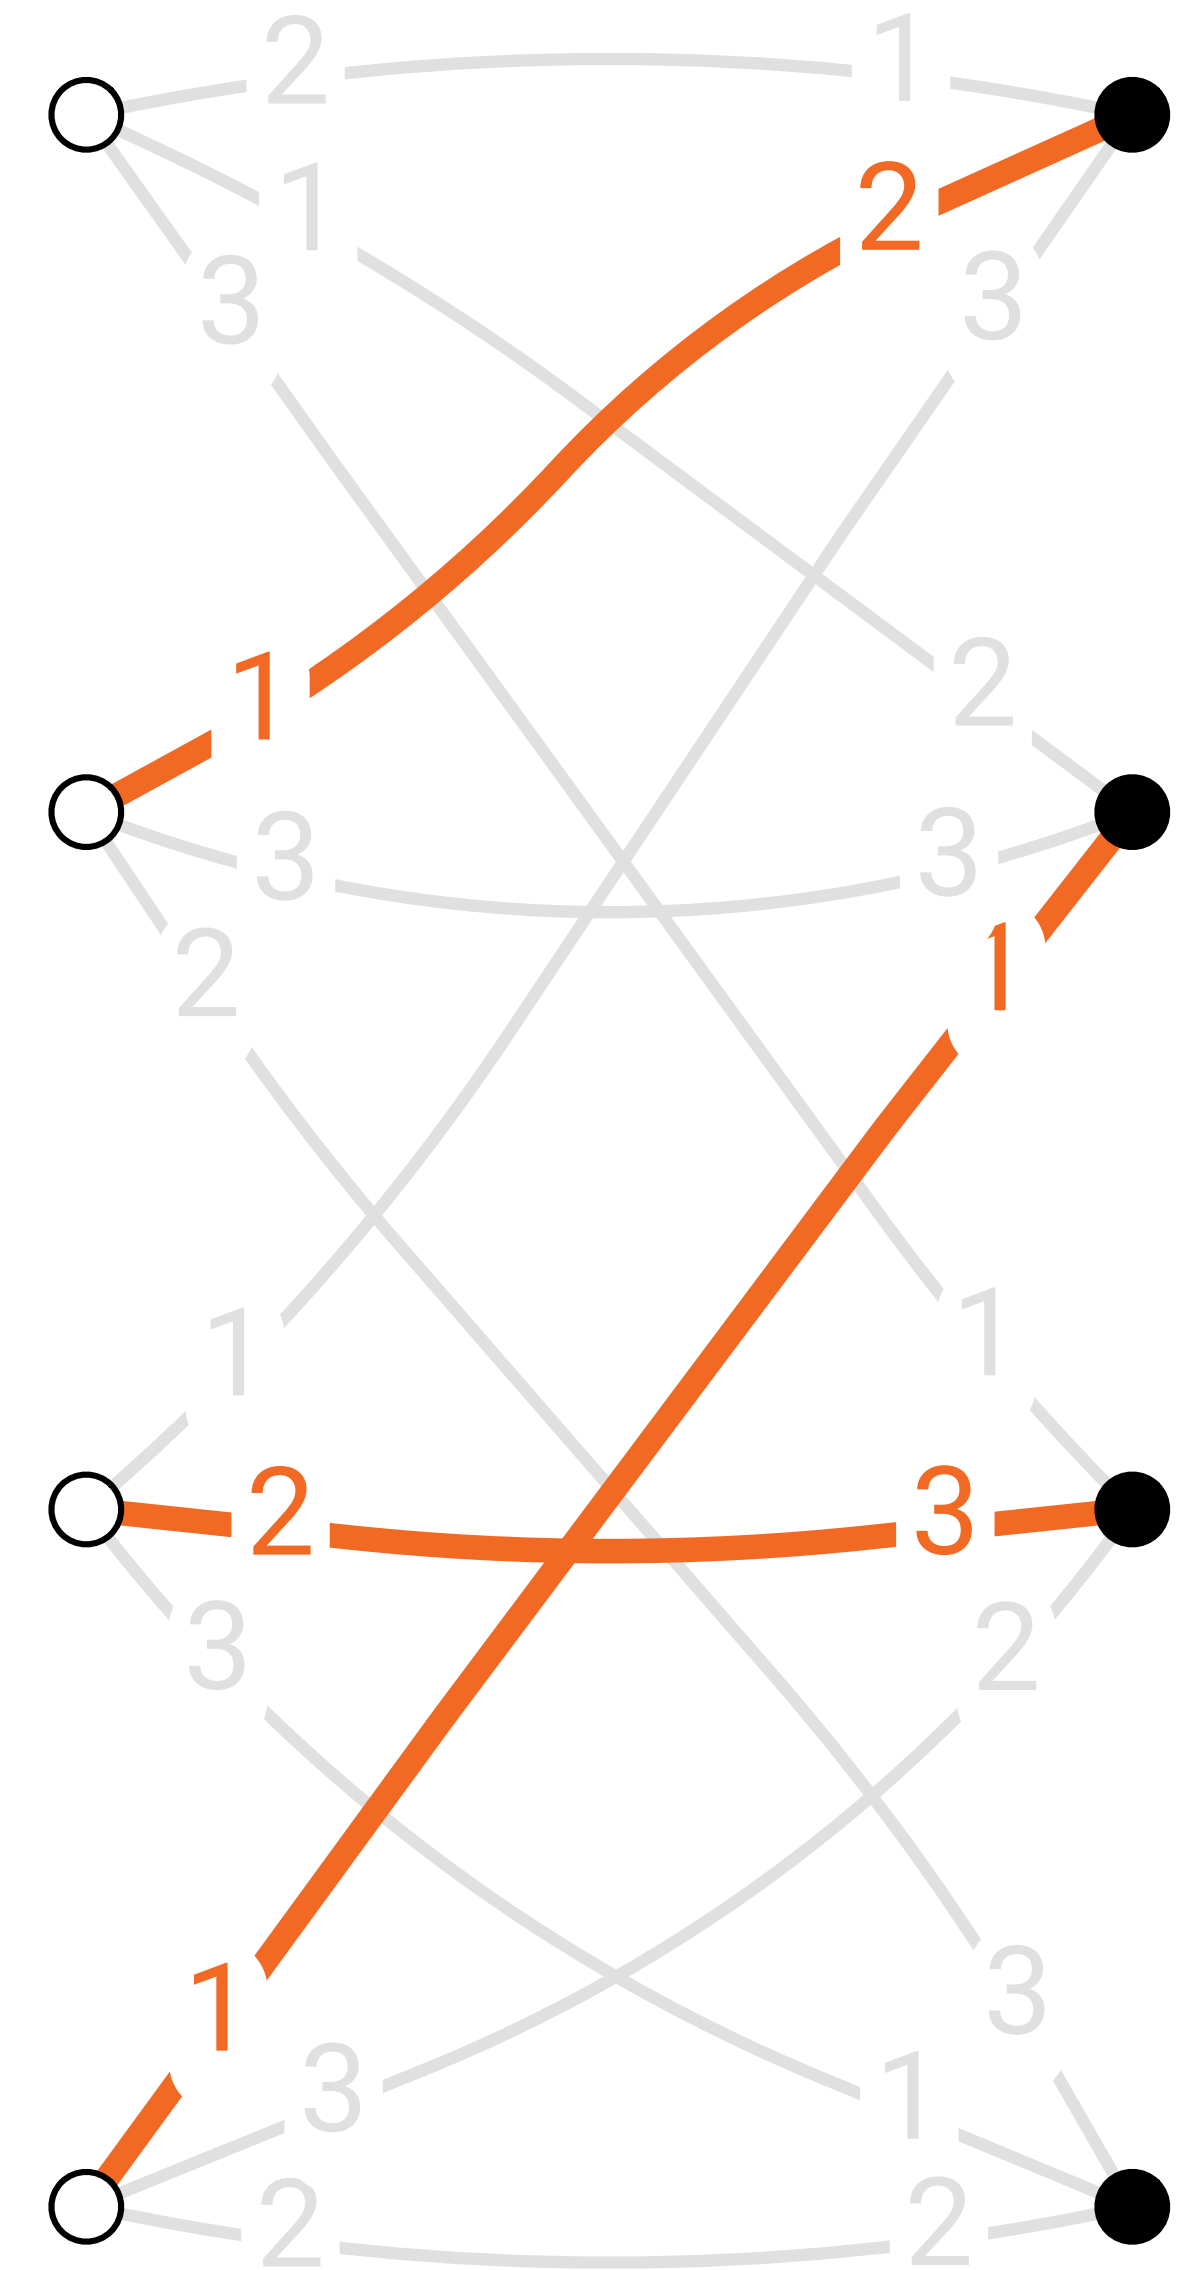

computer network with port numbering

bipartite, 2-colored graph

Δ -regular (here $\Delta = 3$)

output: *maximal matching*

Very simple algorithm

unmatched white nodes:
 send *proposal* to port 1

Very simple algorithm

unmatched white nodes:
send *proposal* to port 1

black nodes:
accept the first proposal you get,
reject everything else
(break ties with port numbers)

Very simple algorithm

unmatched white nodes:
send *proposal* to port 1

black nodes:
accept the first proposal you
get, *reject* everything else
(break ties with port numbers)

Very simple algorithm

unmatched white nodes:
send *proposal* to port 2

Very simple algorithm

unmatched white nodes:
send *proposal* to port 2

black nodes:
accept the first proposal you
get, *reject* everything else
(break ties with port numbers)

Very simple algorithm

unmatched white nodes:
send *proposal* to port 2

black nodes:
accept the first proposal you
get, *reject* everything else
(break ties with port numbers)

Very simple algorithm

unmatched white nodes:
send *proposal* to port 3

Very simple algorithm

unmatched white nodes:
send *proposal* to port 3

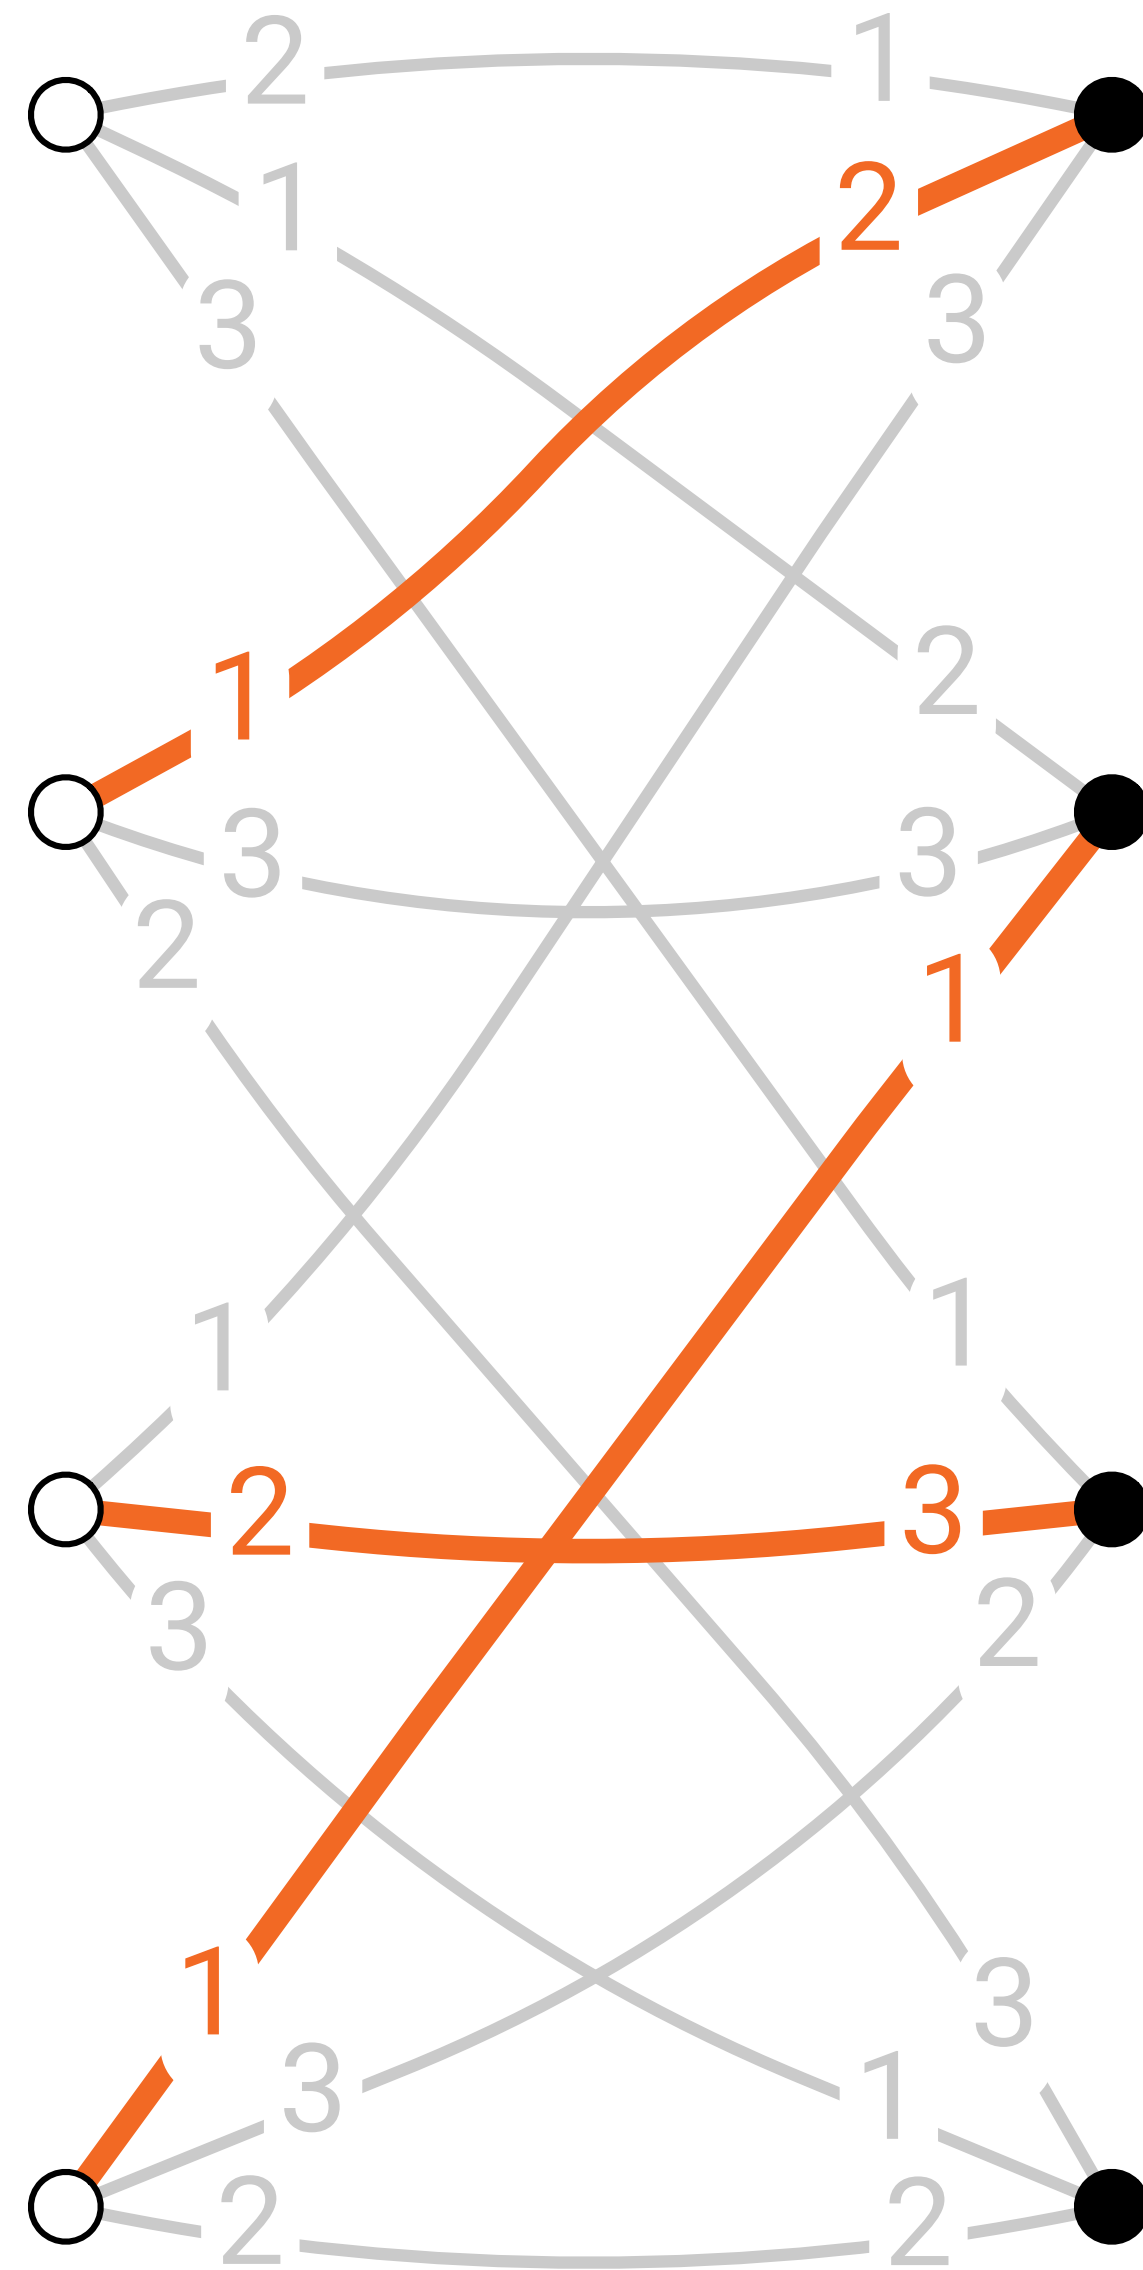

black nodes:
accept the first proposal you get,
reject everything else
(break ties with port numbers)

Very simple algorithm

unmatched white nodes:
send *proposal* to port 3

black nodes:
accept the first proposal you
get, *reject* everything else
(break ties with port numbers)

Very simple algorithm

Finds a *maximal matching* in $O(\Delta)$ communication rounds

Note: running time does not depend on n

Bipartite maximal matching

- Maximal matching in very large 2-colored Δ -regular graphs
- Simple algorithm: **$O(\Delta)$ rounds**, independently of n
- ***Is this optimal?***
 - $o(\Delta)$ rounds?
 - $O(\log \Delta)$ rounds?
 - 4 rounds??

Big picture

Bounded-degree graphs & LOCAL model

LOCAL model

- Each node has a **unique identifier** from 1 to $\text{poly}(n)$
- **No bounds** on the computational power
- **No bounds** on the bandwidth
- **Synchronous** model
- **Everything** can be solved in **Diameter** time

Strong model – lower bounds widely applicable

**Maximal matching,
LOCAL model,
 $O(f(\Delta) + g(n))$**

Algorithms:

- deterministic
- randomized

Lower bounds:

- deterministic
- randomized

**Maximal matching,
LOCAL model,
 $O(f(\Delta) + g(n))$**

Algorithms:

○ deterministic

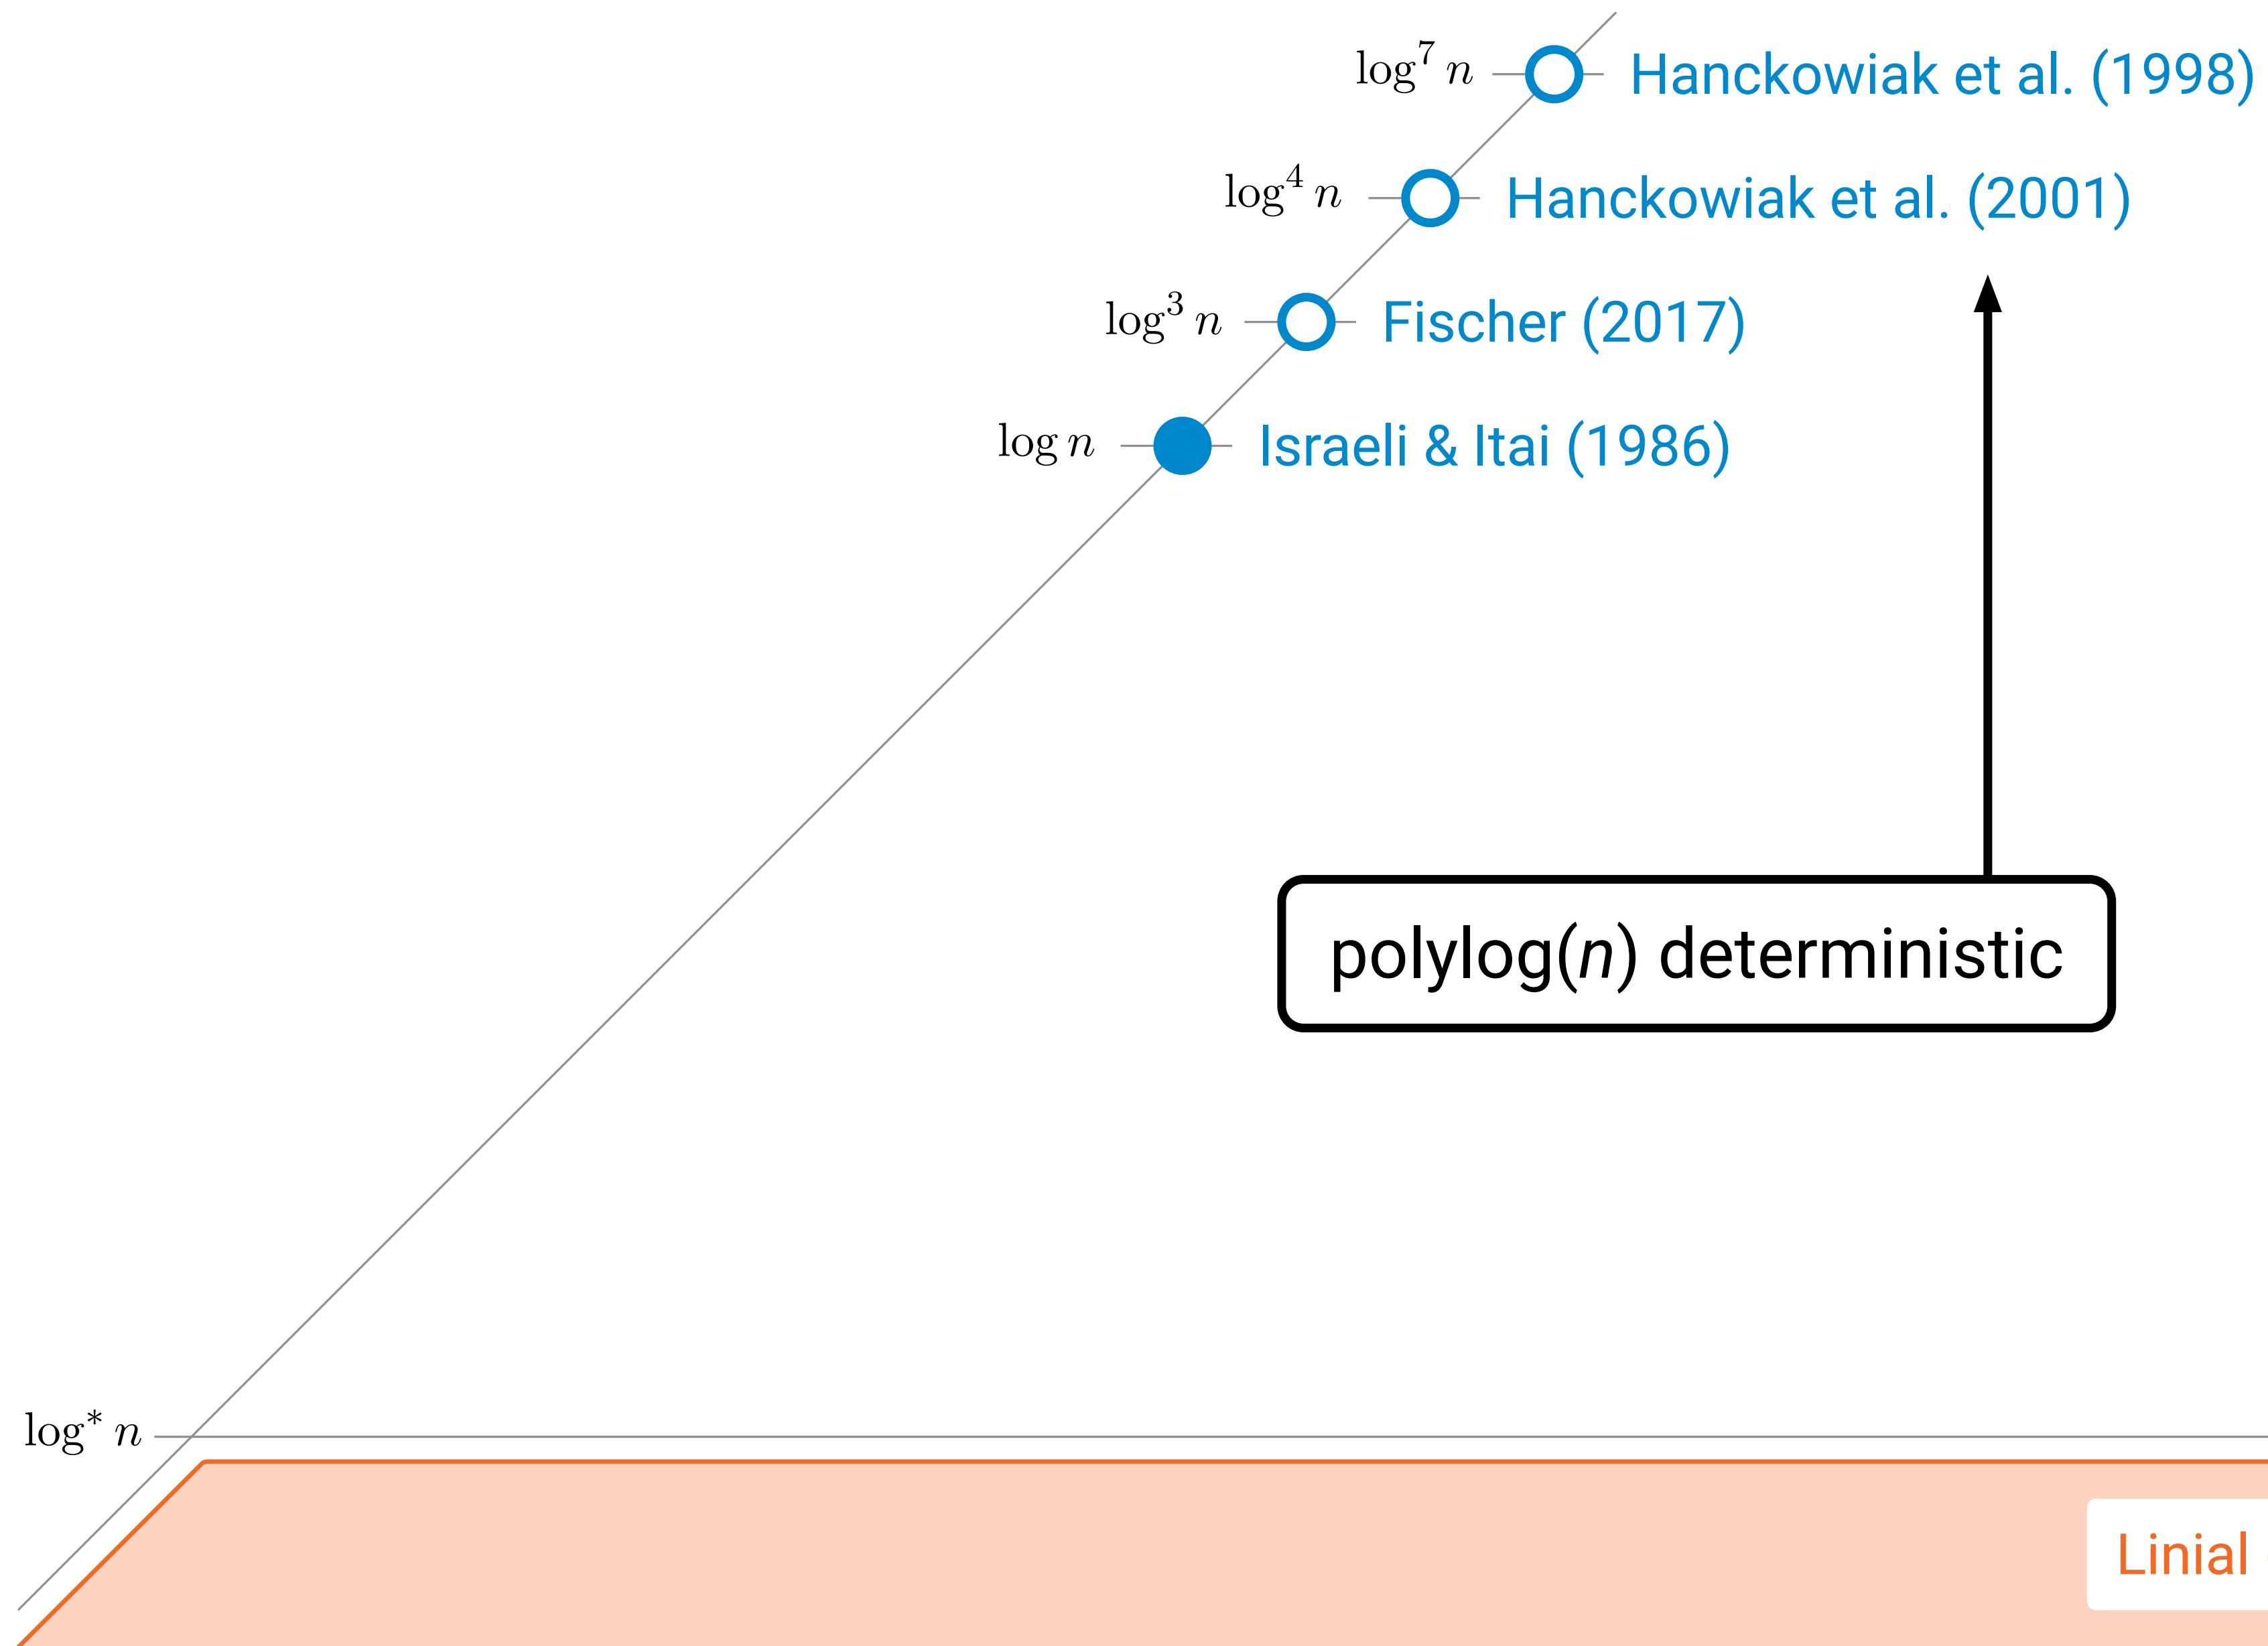

● randomized

Lower bounds:

□ deterministic

■ randomized

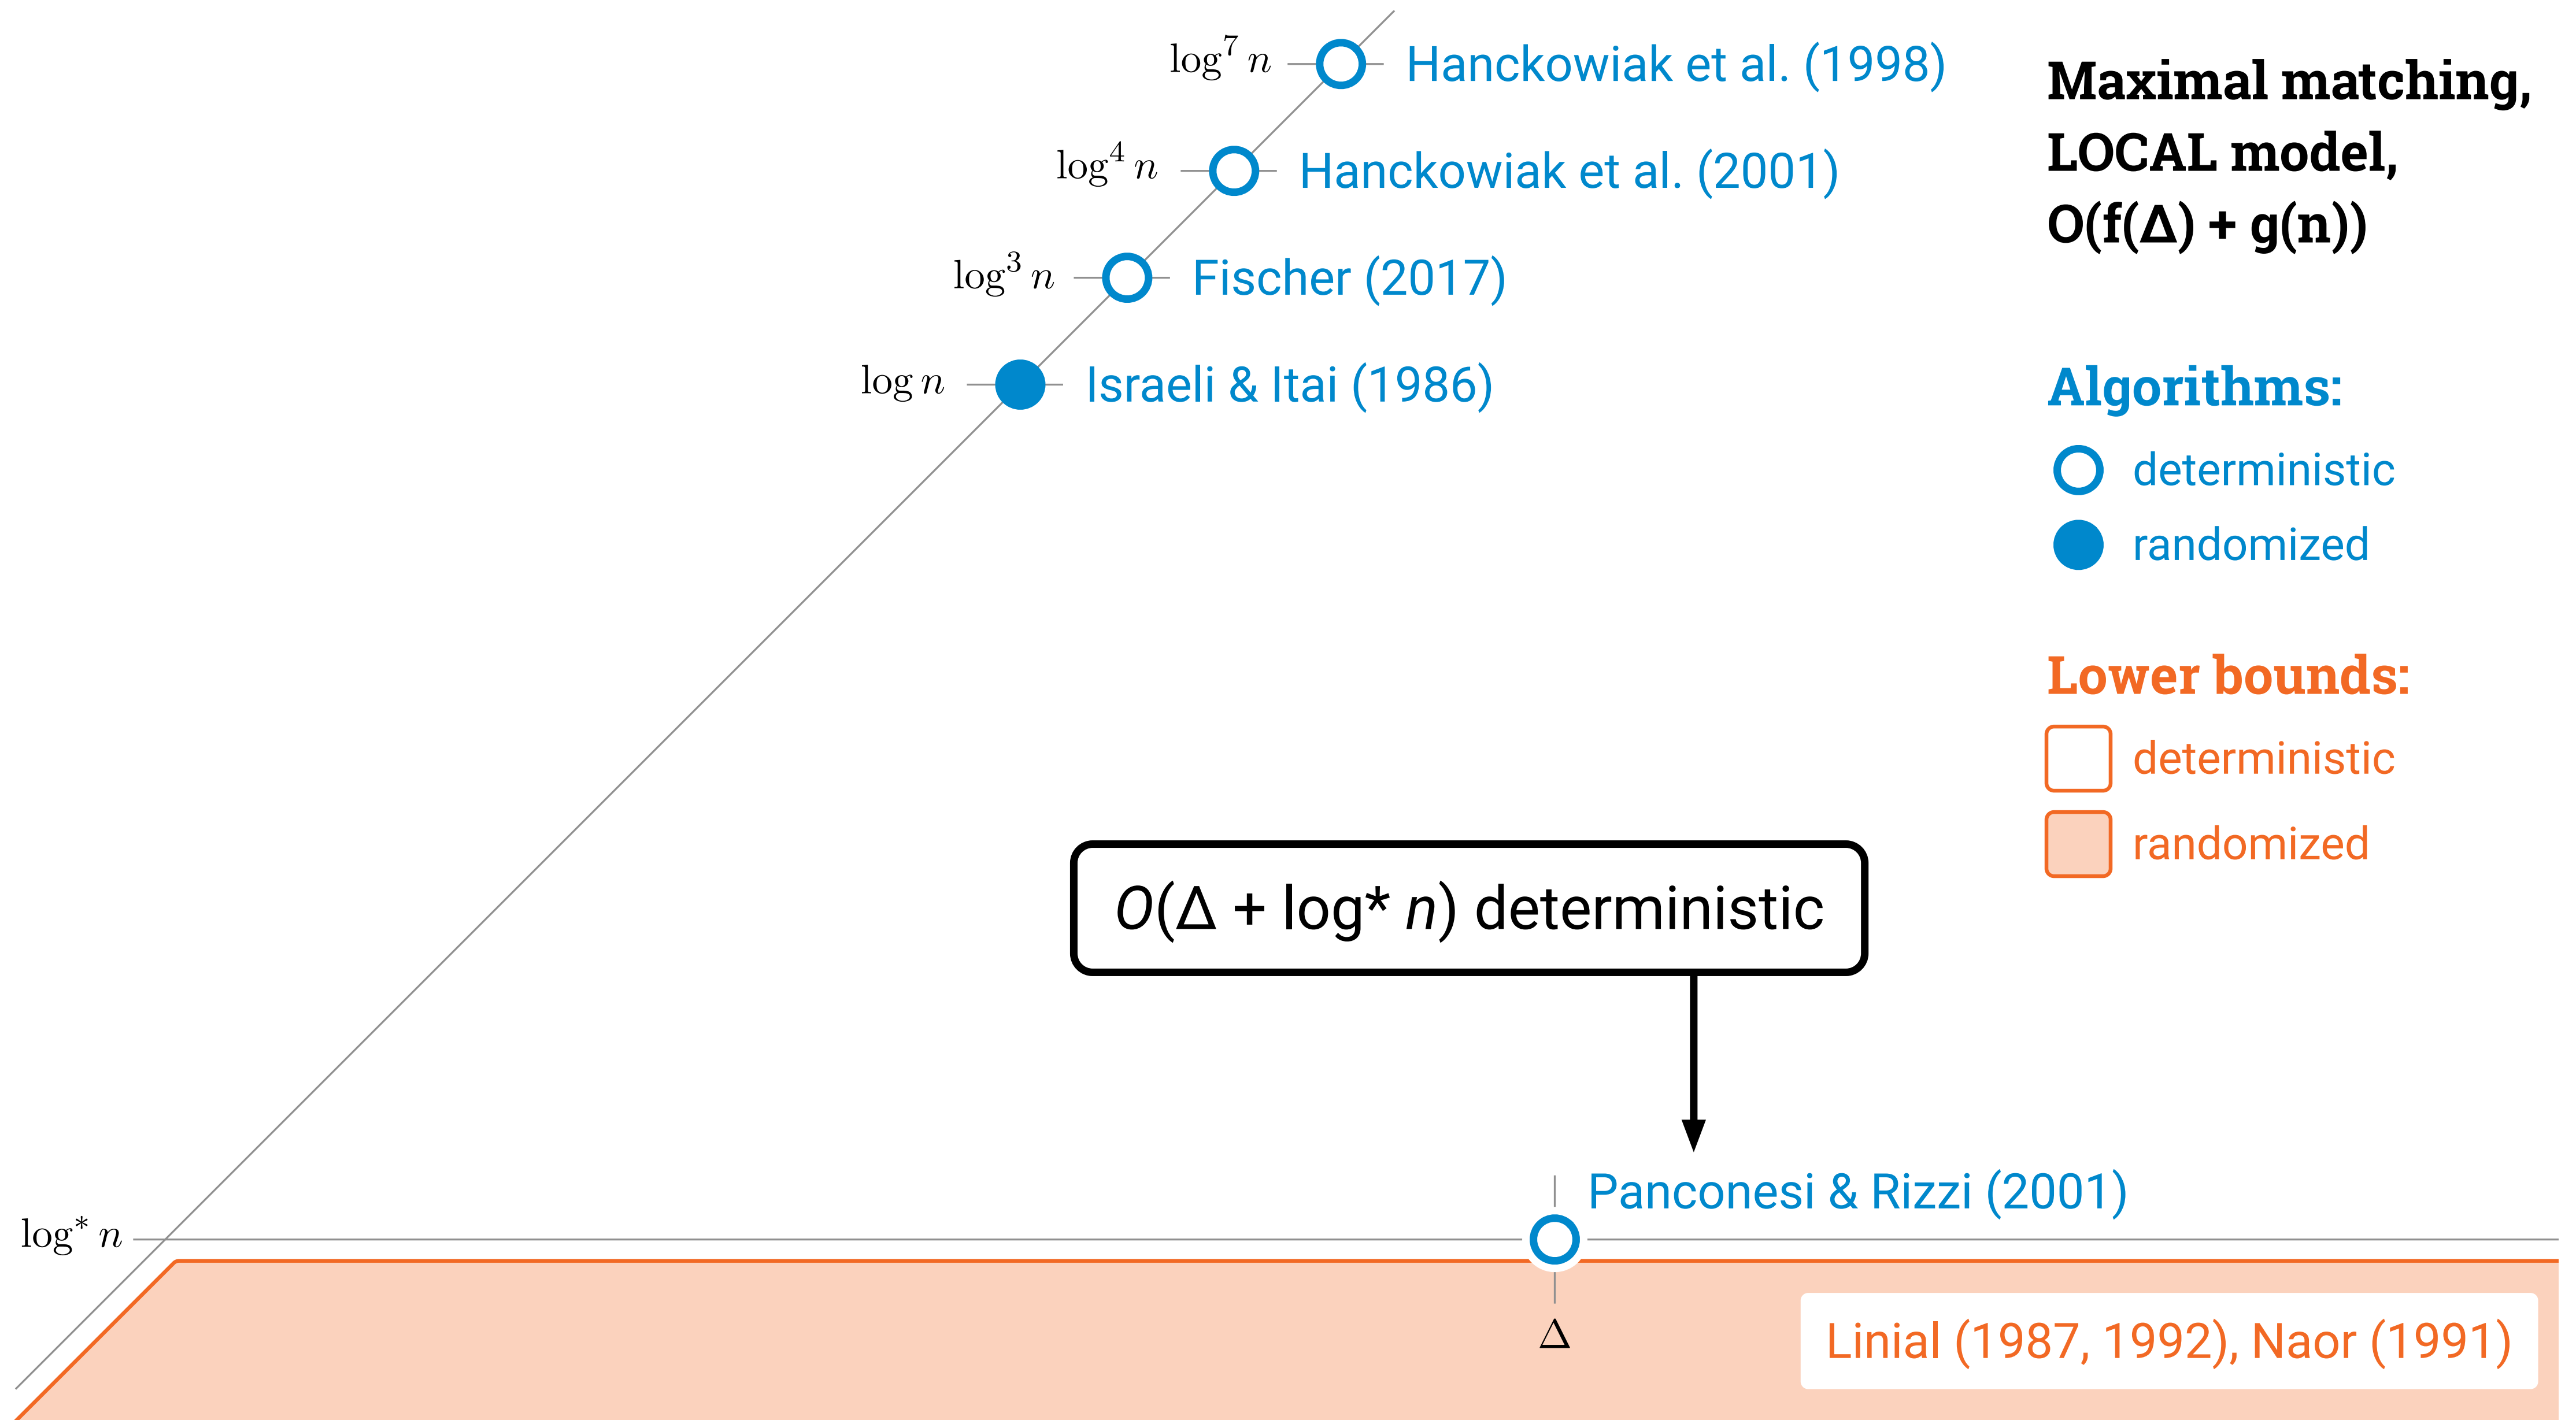

**Maximal matching,
LOCAL model,
 $O(f(\Delta) + g(n))$**

Algorithms:

- deterministic
- randomized

Lower bounds:

Lower bounds:

- deterministic
- randomized

**Maximal matching,
LOCAL model,
 $O(f(\Delta) + g(n))$**

Algorithms:

- deterministic
- randomized

Lower bounds:

- deterministic
- randomized

Main results

Maximal Matching and Maximal Independent Set cannot be solved in

- $o(\Delta + \log \log n / \log \log \log n)$ rounds with randomized algorithms, in the LOCAL model
- $o(\Delta + \log n / \log \log n)$ rounds with deterministic algorithms, in the LOCAL model

Upper bound:
 $O(\Delta + \log^* n)$

This is optimal!

Very simple algorithm

unmatched white nodes:
send *proposal* to port 1

black nodes:
accept the first proposal you get,
reject everything else
(break ties with port numbers)

Lower bound for MM implies lower bound for MIS

An algorithm for **MIS** implies an algorithm for **MM**

Lower bound for MM implies lower bound for MIS

An algorithm for **MIS** implies an algorithm for **MM**

Lower bound for MM implies lower bound for MIS

An algorithm for **MIS** implies an algorithm for **MM**

Lower bound for MM implies lower bound for MIS

An algorithm for **MIS** implies an algorithm for **MM**

If we **cannot solve MM in $o(\Delta)$** , then we **cannot solve MIS in $o(\Delta)$**

Proof techniques

Round elimination

Round elimination technique

- **Given:**
 - algorithm A_0 solves problem P_0 in T rounds
- **We construct:**
 - algorithm A_1 solves problem P_1 in $T - 1$ rounds
 - algorithm A_2 solves problem P_2 in $T - 2$ rounds
 - algorithm A_3 solves problem P_3 in $T - 3$ rounds
 - ...
 - algorithm A_T solves problem P_T in 0 rounds
- But P_T is nontrivial, so A_0 cannot exist

Linial (1987, 1992): coloring cycles

- **Given:**
 - algorithm A_0 solves **3-coloring** in $T = o(\log^* n)$ rounds
- **We construct:**
 - algorithm A_1 solves **2^3 -coloring** in $T - 1$ rounds
 - algorithm A_2 solves **2^{2^3} -coloring** in $T - 2$ rounds
 - algorithm A_3 solves **$2^{2^{2^3}}$ -coloring** in $T - 3$ rounds
 - ...
 - algorithm A_T solves **$o(n)$ -coloring** in **0** rounds
- But **$o(n)$ -coloring** is nontrivial, so A_0 cannot exist

Linial (1987, 1992): coloring cycles

- **Given:**
 - algorithm A_0 solves **3-coloring** in $T = o(\log^* n)$ rounds
- **We construct:**
 - algorithm A_1 solves **2^3 -coloring** in $T - 1$ rounds
 - algorithm A_2 solves **2^{2^3} -coloring** in $T - 2$ rounds
 - algorithm A_3 solves **$2^{2^{2^3}}$ -coloring** in $T - 3$ rounds
 - ...
 - algorithm A_T solves **$o(n)$ -coloring** in **0** rounds
- But **$o(n)$ -coloring** is nontrivial, so A_0 cannot exist

Challenge:
discover P_i

Round elimination technique

- **Given:**
 - algorithm A_0 solves problem P_0 in T rounds
- **We construct:**
 - algorithm A_1 solves problem P_1 in $T - 1$ rounds
 - algorithm A_2 solves problem P_2 in $T - 2$ rounds
 - algorithm A_3 solves problem P_3 in $T - 3$ rounds
 - ...
 - algorithm A_T solves problem P_T in 0 rounds
- But P_T is nontrivial, so A_0 cannot exist

Given any P_i , it is possible to find P_{i+1} automatically, but the description of the problem may grow exponentially

[Brandt, 2019]

Round elimination technique

- **Given:**
 - algorithm A_0 solves problem P_0 in T rounds
- **We construct:**
 - algorithm A_1 solves problem P_1 in $T - 1$ rounds
 - algorithm A_2 solves problem P_2 in $T - 2$ rounds
 - algorithm A_3 solves problem P_3 in $T - 3$ rounds
 - ...
 - algorithm A_T solves problem P_T in 0 rounds
- But P_T is nontrivial, so A_0 cannot exist

Challenge:
keep P_i small

Round elimination technique for MM

- **Given:**
 - algorithm A_0 solves problem $P_0 = \text{maximal matching}$ in T rounds
- **We construct:**
 - algorithm A_1 solves problem P_1 in $T - 1$ rounds
 - algorithm A_2 solves problem P_2 in $T - 2$ rounds
 - algorithm A_3 solves problem P_3 in $T - 3$ rounds
 - ...
 - algorithm A_T solves problem P_T in 0 rounds
- But P_T is nontrivial, so A_0 cannot exist

What are
these
problems
 P_i here?

General approach

Maximal matching in $o(\Delta)$ rounds

What we really care about

General approach

Maximal matching in $o(\Delta)$ rounds

→ “ $\Delta^{1/2}$ matching” in $o(\Delta^{1/2})$ rounds

What we really care about

k-matching:
select at most
k edges per node

General approach

Maximal matching in $o(\Delta)$ rounds

→ “ $\Delta^{1/2}$ matching” in $o(\Delta^{1/2})$ rounds

→ $P(\Delta^{1/2}, 0)$ in $o(\Delta^{1/2})$ rounds

What we really care about

k-matching:
select at most
k edges per node

General approach

Maximal matching in $o(\Delta)$ rounds

→ “ $\Delta^{1/2}$ matching” in $o(\Delta^{1/2})$ rounds

→ $P(\Delta^{1/2}, 0)$ in $o(\Delta^{1/2})$ rounds

What we really care about

k-matching:
select at most
k edges per node

Apply round
elimination
 $o(\Delta^{1/2})$ times

General approach

Maximal matching in $o(\Delta)$ rounds

→ “ $\Delta^{1/2}$ matching” in $o(\Delta^{1/2})$ rounds

→ $P(\Delta^{1/2}, 0)$ in $o(\Delta^{1/2})$ rounds

→ $P(O(\Delta^{1/2}), o(\Delta))$ in 0 rounds

→ contradiction

What we really care about

k-matching:
select at most
k edges per node

Apply round
elimination
 $o(\Delta^{1/2})$ times

Representation for maximal matchings

white nodes “active”

output one of these:

- $1 \times M$ and $(\Delta-1) \times O$
- $\Delta \times P$

$$W = MO^{\Delta-1} \mid P^{\Delta}$$

- M = “matched”
- P = “pointer to matched”
- O = “other”

black nodes “passive”

accept one of these:

- $1 \times M$ and $(\Delta-1) \times \{P, O\}$
- $\Delta \times O$

$$B = M[PO]^{\Delta-1} \mid O^{\Delta}$$

Parametrized problem family

$$W = MO^{\Delta-1} \mid P^{\Delta},$$

$$B = M[PO]^{\Delta-1} \mid O^{\Delta}$$

maximal matching

$$W_{\Delta}(x, y) = \left(MO^{d-1} \mid P^d \right) O^y X^x,$$

“weak” matching

$$B_{\Delta}(x, y) = \left([MX][POX]^{d-1} \mid [OX]^d \right) [POX]^y [MPOX]^x,$$

$$d = \Delta - x - y$$

Parametrized problem family

$$W = MO^{\Delta-1} \mid P^{\Delta},$$

$$B = M[PO]^{\Delta-1} \mid O^{\Delta}$$

maximal matching

$$W_{\Delta}(x, y) = \left(MO^{d-1} \mid P^d \right) O^y X^x,$$

“weak” matching

A node v can be matched with at most x neighbours
If v is not matched, at most y neighbours can be unmatched

Main Lemma

- Given: \mathbf{A} solves $P(x, y)$ in T rounds
- We can construct: \mathbf{A}' solves $P(x + 1, y + x)$ in $T - 1$ rounds

$$W_{\Delta}(x, y) = \left(\mathbf{M}\mathbf{O}^{d-1} \mid \mathbf{P}^d \right) \mathbf{O}^y \mathbf{X}^x,$$

$$B_{\Delta}(x, y) = \left([\mathbf{M}\mathbf{X}][\mathbf{P}\mathbf{O}\mathbf{X}]^{d-1} \mid [\mathbf{O}\mathbf{X}]^d \right) [\mathbf{P}\mathbf{O}\mathbf{X}]^y [\mathbf{M}\mathbf{P}\mathbf{O}\mathbf{X}]^x,$$

$$d = \Delta - x - y$$

Putting things together

Proof technique does not work directly with unique IDs

- Basic version:
 - deterministic lower bound, *port-numbering model*
- Analyze what happens to local failure probability:
 - *randomized* lower bound, port-numbering model
- With randomness you can construct unique identifiers w.h.p.:
 - randomized lower bound, *LOCAL model*
- Fast deterministic → very fast randomized
 - stronger *deterministic* lower bound, LOCAL model

Summary

- ***Linear-in- Δ lower bounds*** for **maximal matchings** and **maximal independent sets**
- Old: can be solved in $O(\Delta + \log^* n)$ rounds
- New: cannot be solved in
 - $o(\Delta + \log \log n / \log \log \log n)$ rounds with randomized algorithms
 - $o(\Delta + \log n / \log \log n)$ rounds with deterministic algorithms
- Technique: ***round elimination***

Clear

Some open questions

- Complexity of $(\Delta+1)$ -vertex coloring?
 - can be solved in $\tilde{O}(\Delta^{1/2}) + O(\log^* n)$ rounds [Fraigniaud et al., 2016]
 - cannot be solved in $o(\log^* n)$ rounds [Linial, 1987]
 - example: is it solvable in $O(\log \Delta + \log^* n)$ time?
- Better understanding of the **round elimination technique**
