- Definition:
  - Given a property P
  - Given a graph G
  - Does G satisfy the property P?
- Example:
  - ▶ Given a graph G
  - Given an integer k
  - Is the graph k colorable?
- Often decision problems are hard
- Sometimes the input is huge, even linear time could be too much

-----

## Property testing

- Relax the requirements
- Given a property P
- Given a graph G
- Distinguish whether:
  - Does G satisfy the property P?
  - ► Is G far from satisfying the property P?
- The input is huge:
  - Only a small part of the input can be seen
  - We want sublinear algorithms

< 3 > < 3 >

### Example: 2 colorability

2 colorable

Far from being 2 colorable

Almost 2 colorable

How to measure how far is a graph from satisfying a property?

Let G = (V, E), n = |V|, m = |E|. Let  $\epsilon$  be a small constant in (0, 1). There exist two distinct models:

## Definition

#### Property Tester (2 sided error)

A tester for a graph property P is a randomized algorithm A that is required to accept or reject any given network instance, under the following two constraints:

- G satisfies  $P \Rightarrow Pr[A \text{ accepts } G] \ge \frac{2}{3}$
- G is  $\epsilon$ -far from satisfying  $P \Rightarrow Pr[A \text{ rejects } G] \ge \frac{2}{3}$

### A weaker lemma that holds in the sparse model

#### Lemma [Fraigniaud, Rapaport, Salo, Todinca '16]

Let *H* be any graph. Let *G* be an *m*-edge graph that is  $\epsilon$ -far from being *H*-free. Then *G* contains at least  $\epsilon m/|E(H)|$  edge-disjoint copies of *H*.

### A weaker lemma that holds in the sparse model

#### Lemma [Fraigniaud, Rapaport, Salo, Todinca '16]

Let *H* be any graph. Let *G* be an *m*-edge graph that is  $\epsilon$ -far from being *H*-free. Then *G* contains at least  $\epsilon m/|E(H)|$  edge-disjoint copies of *H*.

The number of copies of H is proportional to m instead of  $n^{|V(H)|}$ , in the sparse model the problem is harder, in fact:

Lemma [Alon, Kaufman, Krivelevich, Ron '08]

Testing triangle freeness requires  $\Omega(n^{\frac{1}{3}})$  queries.

# Distributed property testing

#### Definition

A distributed tester for a graph property P is a distributed randomized algorithm A that satisfies the following conditions:

- G satisfies  $P \Rightarrow$  every node outputs "accept"
- *G* is  $\epsilon$ -far from satisfying  $P \Rightarrow$ Pr[at least one node outputs "reject"]  $\geq \frac{2}{3}$

. . . . . . . .

- All nodes start the computation at the same round
- The computation proceeds in phases
- At each phase each node:

< 3 > < 3 >

### The Congest Model

- All nodes start the computation at the same round
- The computation proceeds in phases
- At each phase each node:
  - sends (possibly different) messages to its neighbors

## The Congest Model

- All nodes start the computation at the same round
- The computation proceeds in phases
- At each phase each node:
  - sends (possibly different) messages to its neighbors
  - receives messages sent by its neighbors

## The Congest Model

- All nodes start the computation at the same round
- The computation proceeds in phases
- At each phase each node:
  - sends (possibly different) messages to its neighbors
  - receives messages sent by its neighbors
  - performs some local computation

- The main constraint of the Congest model is that the exchanged messages should be small, typically  $O(\log n)$ .
- For example, messages of size  $O(\log n)$  are enough to transmit, in a single round, a constant number of IDs of neighbors.

. . . . . . . .

## Decision problems in the Congest model

It is difficult to decide distributedly if a graph satisfies a property in constant time because of:

- Locality: two nodes can communicate in a time proportional to their distance
- Congestion: a node can not communicate all its neighbors to a single neighbor because they could be many

Example: knowing if a ring is 2 colorable requires to know the parity of its size.

• • = • • = •

Knowing the 2-hop neighborhood is hard

### Dense model

### Lemma [Censor-Hillel, Fischer, Schwartzman, Vasudev '16] Any $\epsilon$ -tester for the dense model (for a non-disjointed property) that makes q queries can be converted to a distributed $\epsilon$ -tester that requires $O(q^2)$ rounds in the distributed setting.

• • = • • = •

### Dense model

## Lemma [Censor-Hillel, Fischer, Schwartzman, Vasudev '16]

Any  $\epsilon$ -tester for the dense model (for a non-disjointed property) that makes q queries can be converted to a distributed  $\epsilon$ -tester that requires  $O(q^2)$  rounds in the distributed setting.

Example of properties testable in constant time:

- Is G *H*-free?
- Is G k-colorable?
- Is G a perfect graph?

## Sparse model

#### [Censor-Hillel, Fischer, Schwartzman, Vasudev '16]

- Triangle freeness can be tested in  $O(1/\epsilon^2)$
- Cycle freeness can be tested  $O(\log n/\epsilon)$
- Cycle freeness requires at least Ω(log n)
- Bipartiteness can be tested in in  $O(poly(\log \frac{n}{\epsilon}/\epsilon))$  in bounded degree graphs

#### [Fraigniaud, Rapaport, Salo, Todinca '16]

• *H*-freeness can be tested in constant time for any *H* s.t.  $|V(H)| \le 4$ 

- - E + - E +
- select two neighbors u and v uniformly at random
- ask to *u* if *v* is his neighbor

- select two neighbors u and v uniformly at random
- ask to *u* if *v* is his neighbor

- select two neighbors u and v uniformly at random
- ask to *u* if *v* is his neighbor

- select two neighbors u and v uniformly at random
- ask to *u* if *v* is his neighbor

Generalization of the procedure: DFS and BFS testers

Each node:

- chooses some neighbor at random
- sends it to some random neighbor
- samples and propagates the received information

[Fraigniaud, Rapaport, Salo, Todinca '16]

BFS and DFS testers can not detect  $C_k$  and  $K_k$  for  $k \ge 5$ .

## $C_k$ detection

### [Fraigniaud, O. '17]

There exists an  $\epsilon$ -tester for  $C_k$  freeness, for any constant  $k \ge 3$ , that requires  $O(\frac{1}{\epsilon})$  rounds in the CONGEST model.

過 ト イヨ ト イヨト

# $C_k$ detection

### [Fraigniaud, O. '17]

There exists an  $\epsilon$ -tester for  $C_k$  freeness, for any constant  $k \ge 3$ , that requires  $O(\frac{1}{\epsilon})$  rounds in the CONGEST model.

Procedure:

- Choose an edge u.a.r.
- Check if there is a cycle of length k passing through that edge
  - It can be done deterministically

• • = • • = •

#### Lemma [Fraigniaud, Rapaport, Salo, Todinca '16]

Let *H* be any graph. Let *G* be an *m*-edge graph that is  $\epsilon$ -far from being *H*-free. Then *G* contains at least  $\epsilon m/|E(H)|$  edge-disjoint copies of *H*.

This implies that by choosing a random edge we have probability  $\Omega(\epsilon)$  to choose an edge that is part of some copy of H.

- Each node picks a random weight w from  $[1, m^2]$  for each edge incident to him
- The "leader" of each edge is the endpoint that chose the smaller weight
- If a node is the leader of multiple edges, choose the one with smaller weight
- Broadcast the edge of known minimum weight, and its weight, for a constant number of rounds

### Check the presence of a cycle

Naïve solution:

- The endpoints of the chosen edge broadcast their id
- Repeat
  - Append my id to each received sequence
  - Broadcast the new sequences just created
  - Check if two sequences are disjoint and form a cycle of desired length

## Example: triangle freeness

Repeat  $O(\frac{1}{\epsilon})$  times:

- Choose an edge (u, v) as described before
- u and v broadcast
- If a node receives two messages a triangle is detected

- 4 3 6 4 3 6

## $C_5$ detection

Node 4:

- receives (1,5), (3,5), (1,6)
- detects (1, 6, 4, 5, 3)

• • = • • = •

### $C_7$ detection

- Nodes at distance 2 could potentially receive  $\Theta(n)$  messages
- The previous procedure could require a lot of bandwidth

- 4 週 ト - 4 三 ト - 4 三 ト

## $C_7$ detection

- The partial solution can be sparsified
- For  $C_7$ , 3 subpaths (for each initial node) are enough

• • = • • = •

# Sparsification of the intermediate solution

#### Lemma [Erdős, Hajnal, Moon '64]

Let V be a set of size n, and consider two integer parameters p and q. For any set  $F \subseteq \mathcal{P}(V)$  of subsets of size at most p of V, there exists a compact (p,q)-representation of F, i.e., a subset  $\hat{F}$  of F satisfying:

• For each set  $C \subseteq V$  of size at most q, if there is a set  $L \in F$  such that  $L \cap C = \emptyset$ , then there also exists  $\hat{L} \in \hat{F}$  such that  $\hat{L} \cap C = \emptyset$ ;

② The cardinality of 
$$\hat{F}$$
 is at most  ${p+q \choose p}$ , for any  $n \geq p+q$  .

In other words, the number of subpaths that must be forwarded at each round do not depend on the size of the graph.

### Sparsification of the intermediate solution

- Node 2 should send at least one sequence that does not contain x1, x2 and x3
- A constant number of sequences are enough

- Pick a random edge (u, v)
- Each node picks a random color from [1, k]
- with constant probability the nodes of a cycle going from *u* to *v* will have colors 1, 2, ..., *k*
- Start a BFS from *u*, that at round *i* can pass only on nodes with color *i*
- If the BFS reaches v at round k, a cycle is detected

# Conclusions

- There exists a deterministic algorithm for the CONGEST model that can check the presence of a fixed tree in a constant number of rounds
- There exists an ε-tester for the CONGEST model that can check the presence of a fixed tree + 1 edge in O(1/ε)
- The minimal graph not testable with the above algorithms is  $K_5$
- For distributed property testing, no lower bounds are known!

# Thank you
